### **Aim:**

To Perform Object Segmentation

### **Objective:**

### **1. Image Segmentation with the Watershed algorithm**

To perform object segmentation using the watershed and GrabCut

### **Theory :**

Image segmentation is the process of dividing an image into several disjoint small local areas or cluster sets according to certain rules and principles. The watershed algorithm is a computer vision technique used for image region segmentation. The watershed algorithm uses topographic information to divide an image into multiple segments or regions. The algorithm views an image as a topographic surface, each pixel representing a different height. The watershed algorithm uses this information to identify catchment basins, similar to how water would collect in valleys in a real topographic map. The watershed algorithm identifies the local minima, or the lowest points, in the image. These points are then marked as markers. The algorithm then floods the image with different colors, starting from these marked markers. As the color spreads, it fills up the catchment basins until it reaches the boundaries of the objects or regions in the image. The **catchment basin** in the watershed algorithm refers to a region in the image that is filled by the spreading color starting from a marker. The catchment basin is defined by the boundaries of the object or region in the image and the local minima in the intensity values of the pixels.

## Vidyavaridhi's College of engineering and Technology

### Department of Computer Engineering

The algorithm uses the catchment basins to divide the image into separate regions and then identifies the boundaries between the basins to create a segmentation of the image for object recognition, image analysis, and feature extraction tasks.

The whole process of the watershed algorithm can be summarized in the following steps:

- **Marker placement:** The first step is to place markers on the local minima, or the lowest points, in the image. These markers serve as the starting points for the flooding process.
- **Flooding:** The algorithm then floods the image with different colors, starting from the markers. As the color spreads, it fills up the catchment basins until it reaches the boundaries of the objects or regions in the image.
- **Catchment basin formation:** As the color spreads, the catchment basins are gradually filled, creating a segmentation of the image. The resulting segments or regions are assigned unique colors, which can then be used to identify different objects or features in the image.
- **Boundary identification:** The watershed algorithm uses the boundaries between the different colored regions to identify the objects or regions in the image. The resulting segmentation can be used for object recognition, image analysis, and feature extraction tasks.

Sure Background

Distance Transform

Sure Foreground

## 2. Example of foreground detection with GrabCut

GrabCut is a perfect tool for foreground/background segmentation. The GrabCut algorithm consists of the following steps:

## Vidyavardhini's College of Engineering and Technology

### Department of Computer Engineering

1. A rectangle including the subject(s) of the picture is defined.
2. The area lying outside the rectangle is automatically defined as a background.
3. The data contained in the background is used as a reference to distinguish background areas from foreground areas within the user-defined rectangle.
4. A Gaussian Mixture Model (GMM) models the foreground and background. and labels undefined pixels as probable background and probable foreground.
5. Each pixel in the image is virtually connected to the surrounding pixels through virtual edges, and each edge is assigned a probability of being foreground or background, based on how similar it is in color to the pixels surrounding it
6. Each pixel (or node as it is conceptualized in the algorithm) is connected to either a foreground or a background node
7. After the nodes have been connected to either terminal (the background or foreground, also called the source or sink, respectively), the edges between nodes belonging to different terminals are cut (hence the name, GrabCut). Thus, the image is segmented into two parts. The following figure adequately represents the algorithm:

**Vidyavardhini's College of engineering and Technology**  
**Department of Computer Engineering**

**Code:**

```
import cv2

import numpy as np

from IPython.display import Image, display

from matplotlib import pyplot as plt

# Plot the image

def imshow(img, ax=None):

    if ax is None:

        ret, encoded = cv2.imencode("/content/doremon.jpg", img)

        display(Image(encoded))

    else:

        ax.imshow(cv2.cvtColor(img, cv2.COLOR_BGR2RGB))

        ax.axis('off')

#Image loading

img = cv2.imread("/content/doremon.jpg")

#image grayscale conversion

gray = cv2.cvtColor(img, cv2.COLOR_BGR2GRAY)

# Show image

imshow(img)
```

## Department of Computer Engineering

#Threshold Processing

```
ret,bin_img=cv2.threshold(gray,0,255,cv2.THRESH_BINARY_INV +cv2.THRESH_OTSU)
```

```
imshow(bin_img)
```

## Vidyavardhini's College of engineering and Technology

### Department of Computer Engineering

```
kernel = cv2.getStructuringElement(cv2.MORPH_RECT, (3, 3))  
  
bin_img = cv2.morphologyEx(bin_img, cv2.MORPH_OPEN,  
  
kernel, iterations=2)  
  
imshow(bin_img)
```

```
# Create subplots with 1 row and 2 columns  
  
fig, axes = plt.subplots(nrows=2, ncols=2, figsize=(8, 8))  
  
# sure background area  
  
sure_bg = cv2.dilate(bin_img, kernel, iterations=3)  
  
imshow(sure_bg, axes[0,0])  
  
axes[0, 0].set_title('Sure Background')  
  
# Distance transform  
  
dist = cv2.distanceTransform(bin_img, cv2.DIST_L2, 5)
```

## Vidyavardhini's College of engineering and Technology

### Department of Computer Engineering

```
imshow(dist, axes[0,1])
```

```
axes[0, 1].set_title('Distance Transform')
```

```
#foreground area
```

```
ret, sure_fg = cv2.threshold(dist, 0.5 * dist.max(), 255, cv2.THRESH_BINARY)
```

```
sure_fg = sure_fg.astype(np.uint8)
```

```
imshow(sure_fg, axes[1,0])
```

```
axes[1, 0].set_title('Sure Foreground')
```

```
# unknown area
```

```
unknown = cv2.subtract(sure_bg, sure_fg)
```

```
imshow(unknown, axes[1,1])
```

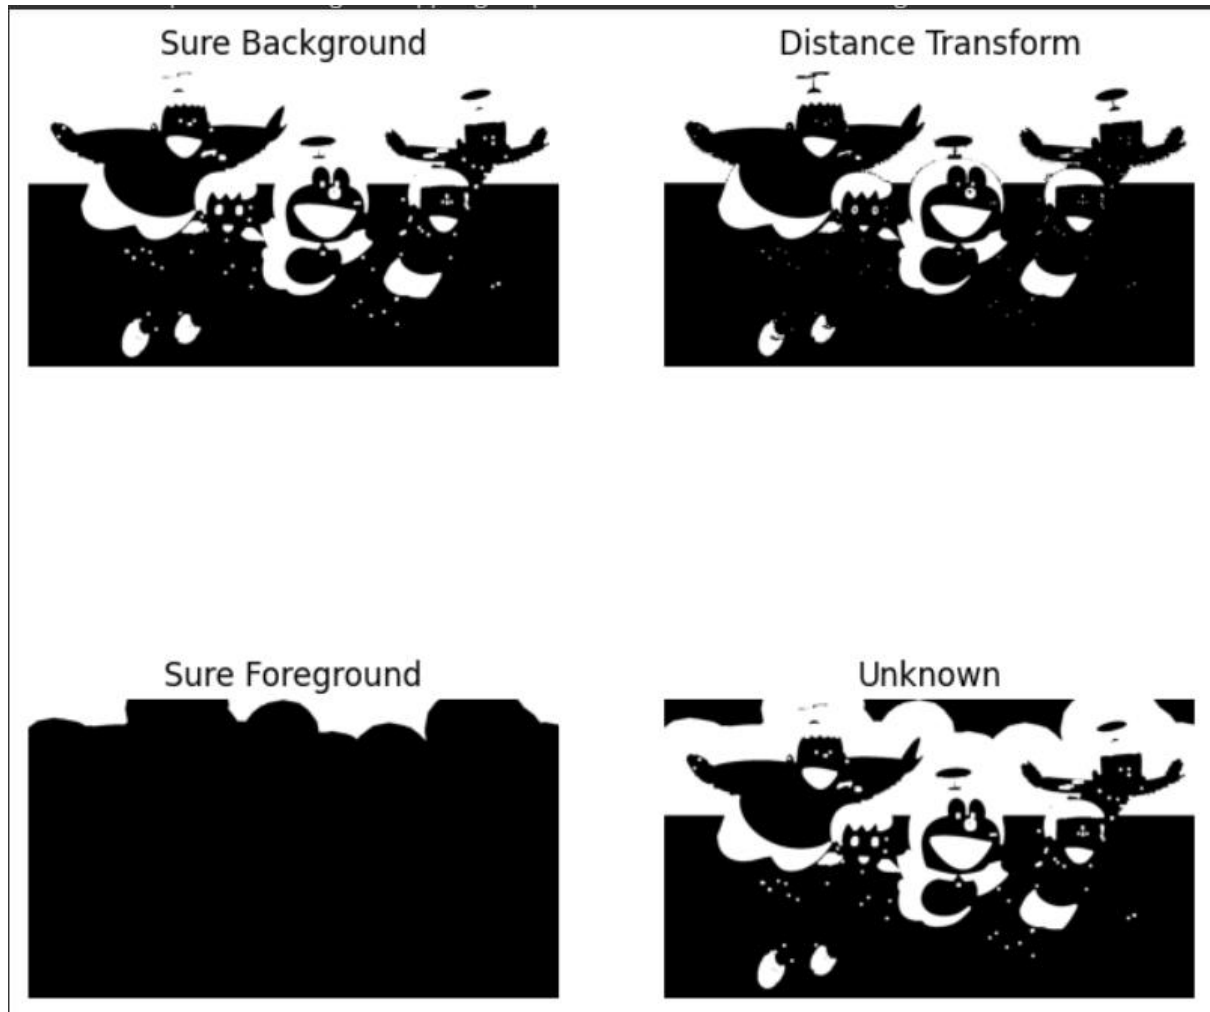

```
axes[1, 1].set_title('Unknown')
```

```
plt.show()
```

### **Conclusion:**

In This Experiment we studied object segmetation using the watershed and GrabCut Algorithm .image segmetation is the process of dividing an image into several disjoint small local areas or cluster sets according to certain rules and principles. The watershed algorithm is a computer vision technique used for image region segmentation and foreground detection with GrabCut GrabCut.
